CS 214: Systems Programming, Spring 2019
Assignment 2: File Compression

Warning: As you will see below, the descriptions of the assignments will be increasingly complex because we are asking you to build increasingly bigger programs. *Make sure to read the assignment carefully!*

0. Abstract
The opendir() and readdir() functions allow you to programmatically traverse through the file system and find/open any file in it (that you have permission to access). File descriptors and open() allow you to read from any file and create file at any point (that you have permission to access). This is quite a bit of power and capability for the very small and direct syntax that is required. The file descriptor abstraction is so generic that once you master its use, you have mastered nearly all basic IO you can do in C. You'll exercise your file manipulation capabilities to first generate Huffman codes for a series of files and then to compress and decompress files with a given Huffman codebook.

1. Introduction
In this assignment you will practice using the file system API and building different data structures to support an algorithm. In particular you will be creating, opening, reading, and writing files and building and traversing various trees and lists. Your task is to write a program that will, based on a command-line switch, either: descend through a directory structure, compute a Huffman code across all files it finds and write out that codebook as a file, or apply a Huffman codebook to a file (or all files it finds), compressing them, or use a Huffman code book to decompress a file (or all files it finds).

1.a. Huffman codes
Huffman codes are a fairly quick way to build a lossless code for data that avoids the prefix problem of dynamically-sized codes, namely that of ambiguity. If you have the tokens, 'a', 'b', 'c', 'd' and assign them the codes 0, 1, 01 and 11, respectively, it is unclear if the code sequence "11" means "bb" or "d". In order to build a Huffman code, you first must count the rate of occurrence of all tokens, sort them, build a Binary Tree out of them, with each token as a leaf. Then traverse the Binary Tree built, recording a '0' for each left branch, '1' for each right branch, assigning the bit sequence generated to each token as a code value. For instance, to build the codebook below:

Word	Frequency	Bit Encoding
a	5	1100
dog	9	1101
cat	12	100
button	13	101
ball	16	111
and	45	0

minheap:
a	5
dog	9
cat	12
button	13
ball	16
and	45

take top 2:
| a | 5 |
| dog | 9 |

build tree0:

14 → a, dog
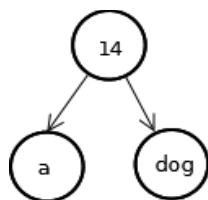

insert node for tree0:
cat	12
button	13
tree0	14
ball	16
and	45

---

minheap:
cat	12
button	13
tree0	14
ball	16
and	45

take top 2:
| cat | 12 |
| button | 13 |

build tree1:

25 → cat, button
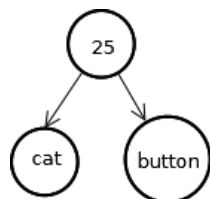

insert node for tree1:
tree0	14
ball	16
tree1	25
and	45

---

minheap:
tree0	14
ball	16
tree1	25
and	45

take top 2:
| tree0 | 14 |
| ball | 16 |

build tree2:

28 → 14, ball; 14 → a, dog
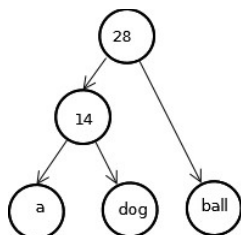

insert node for tree 2:
tree1	25
tree2	28
and	45

---

minheap:
tree1	25
tree2	28
and	45

take top 2:
| tree1 | 25 |
| tree2 | 28 |

build tree3:

53 → 25, 28; 25 → cat, button; 28 → 14, ball; 14 → a, dog
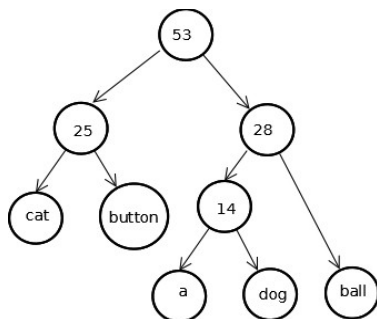

insert node for tree 3:
| and | 45 |
| tree3 | 53 |

---

minheap:
| and | 45 |
| tree3 | 53 |

take top 2:
| and | 45 |
| tree3 | 53 |

build tree4:

99 → and, 53; 53 → 25, 28; 25 → cat, button; 28 → 14, ball; 14 → a, dog
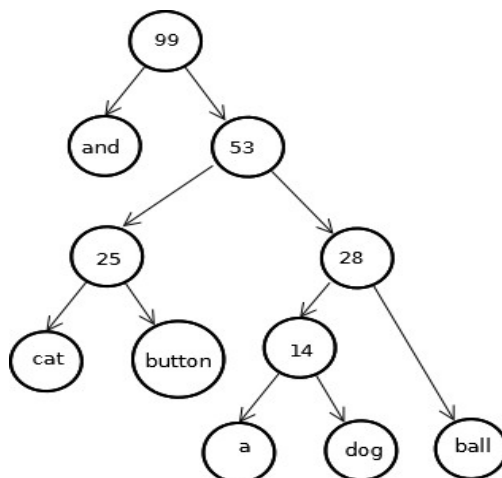

Label each link with '0' for left and '1' for right:
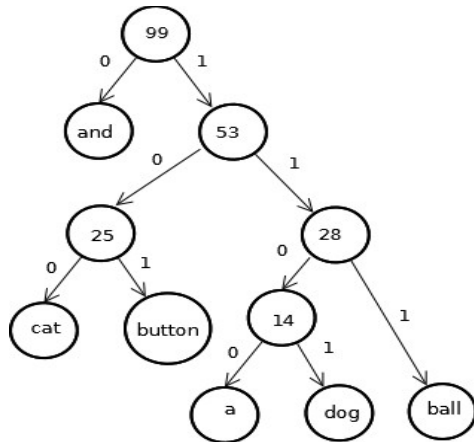

Traverse the tree, recording bit sequence to reach each token:

0	and
100	cat
101	button
1100	a
1101	dog
111	ball

Replace all occurrences of tokens with bit sequences from the codebook:

Test.txt contents: Test.hcz contents:
  a dog and cat   110011010100

       Building a Huffman code will give you a lossless, dynamic-length code with no ambiguity. The code is not informationally optimal, but is optimal in prefix length as it will bias the shorter codes to be used by the tokens that appear most often. Informationally-optimal codes can be built with a somewhat more complex algorithm we won't be covering.

2. Implementation
2.a. Command Line Interface
Your program must implement the following command-line interface:
        `./fileCompressor <flag> <path or file> |codebook|`
Your program must support the following flags: (which may appear in any order, but before any arguments)

b	build codebook:	the fileCompressor will index the file indicated and output a 'HuffmanCodebook' file in the same directory the fileCompressor is invoked in
c	compress:	the fileCompressor will compress the file indicated, <filename>, using the given codebook in to <filename>.hcz alongside the original file
d	decompress:	the fileCompressor will decompress the file indicated, <filename>.hcz, using the given codebook in to <filename> alongside the original file
R	recursive:	including a 'R' argument with any of the above will run them in recursive mode, in which case the file argument will need to be a path and fileCompressor will recursively descend in to that directory and all subdirectories, recursively applying the given operation to all files found

e.g.: ./fileCompressor -R -b ./   recursively index all files found inthe current working directory, all subdirectories and emit a single ./HuffmanCodebook for them

./fileCompressor -d ./dir/test/file.txt.hcz ./HuffmanCodebook
            decompress ./dir/test/file.txt.hcz in to ./dir/test/file.txt using the codebook ./HuffmanCodebook

2.b. HuffmanCodebook format
When building the HuffmanCodebook, it should be in the following format:
|escape char|
<ASCII bytestring>   <tab> <token> <newline>
...
<blank line - newline terminated>

e.g.:
\
0   and
100   cat
101   button
1100   a
1101   dog
111   ball
<blank line - newline terminated>

2.c. Tokenizing
Tokens are defined as any sequence of chars terminated by either a whitespace or newline or other control code.

e.g.:
If a file contains:
        This an$example12 mail@rutgers
It should tokenize to:
        This
        an$example12
        mail@rutgers

Do not include whitespace in your tokens, but you should automatically insert a whitespace after tokens when decompressing a file, except when the token terminates in a newline or other control code. Be careful to detect, encode and be able to insert/print control codes in to files that you decompress. In order to detect control codes you want to insert in to your stored tokens, you can add an escape character to them when you write them in to your codebook. Be sure to pick a character that does not occur in the files you index as an escape character when building your codebook. If you do not need an escape character, feel free not to use one.

Feel free to use the strtok library or other libraries on iLabs to assist you.

3. Methodology
You may want to first code a min-heap and binary tree. If you are going to build a binary tree, it isn't too much farther to build a binary search tree, which will allow you to quickly sort tokens in to your tree (it is not too many steps to convert a BST in to an AVL tree as well, for guaranteed O(lg n) inserts). This can be done in isolation from any other code.

You may want to approach building up your functionality in the following manner
0. Get your program to find all files in a directory and print out their names
1. Get your program to recursively descend down all subdirectories and print out their names with paths
        - open all files and output them to stdout to test
        - open all files and write them to <filename>.test to test
2. Build and test tokenizing static strings in your code
        - count the number of occurrences of each token read in from files
3. Generate a Huffman codebook given a sequence of tokens and frequencies

4. Implement the -b and -R flags and test writing out a Huffman code book
5. ... etc.

4. Results

Submit a tarred gzipped file named Asst2.tgz that contains:

   a directory named Asst2/ that contains the following:
   - all .h and .c files necessary to produce an executable named fileCompressor
   - "Makefile" used to build the fileCompressor executable
      - make sure it has an 'all' target as its first directive, as well as a 'clean' target
   - "testplan.txt" that details the testing you ran your program through
   - "readme.pdf" that describes the design and implementation of your fileCompressor
      - include an analysis of the time and space usage and complexity of your program. You do not
        need to analyze every size function, but you should analyze the overall program's time and
        space used as a function of the size of the input.

Your grade will be based on:

Correctness	(how will your code operates)
Design Quality	(how well your code works)
Code Quality	(how well written and readable your code is)
Efficiency	(asymptotically in time and space)
Testing	(how thorough your cases are)

   Grouping:
      Unless explicitly exempted, you must have a partner, if you do not you will incur a 20pt penalty

      Be sure to sign up on the Google sheet for this assignment, even if you did last time.
      If you do not, you will not receive a grade.
